

THE NEW JERSEY TURFGRASS ASSOCIATION

In Cooperation With RUTGERS COOPERATIVE EXTENSION NEW JERSEY AGRICULTURAL EXPERIMENT STATION RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY NEW BRUNSWICK

Distributed in cooperation with U. S. Department of Agriculture in furtherance of the Acts of Congress on May 8 and June 30, 1914. Rutgers Cooperative Extension works in agriculture, family and consumer sciences, and 4-H. Adesoji O. Adelaja, Director of Extension, Rutgers Cooperative Extension provides information and educational services to all people without regard to race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs.) Rutgers Cooperative Extension is an Equal Opportunity Program Provider and Employer.

2002 RUTGERS TURFGRASS PROCEEDINGS

of the

New Jersey Turfgrass Expo December 10-12, 2002 Trump Taj Mahal Atlantic City, New Jersey

The Rutgers Turfgrass Proceedings is published yearly by the Rutgers Center for Turfgrass Science, Rutgers Cooperative Extension, and the New Jersey Agricultural Experiment Station, Cook College, Rutgers, The State University of New Jersey in cooperation with the New Jersey Turfgrass Association. The purpose of this document is to provide a forum for the dissemination of information and the exchange of ideas and knowledge. The proceedings provide turfgrass managers, research scientists, extension specialists, and industry personnel with opportunities to communicate with co-workers. Through this forum, these professionals also reach a more general audience, which includes the public.

This publication includes lecture notes of papers presented at the 2002 New Jersey Turfgrass Expo. Publication of these lectures provides a readily available source of information covering a wide range of topics and includes technical and popular presentations of importance to the turfgrass industry. This proceedings also includes research papers that contain original research findings and reviews of selected subjects in turfgrass science. These papers are presented primarily to facilitate the timely dissemination of original turfgrass research for use by the turfgrass industry.

Special thanks are given to those who have submitted papers for this proceedings, to the New Jersey Turfgrass Association for financial assistance, and to those individuals who have provided support to the Rutgers Turfgrass Research Program at Cook College, Rutgers, The State University of New Jersey.

INCIDENCE OF NEOTYPHODIUM ENDOPHYTE IN SEED LOTS OF CULTIVARS AND SELECTIONS OF THE 2001 NATIONAL TALL FESCUE TEST

Melissa M. Mohr, William A. Meyer, and Carrie Mansue¹

Since its introduction to the United States in the nineteenth century as a forage grass, tall fescue (*Festuca arundinacea*) has become an increasingly popular cool-season grass in the turf industry. Extensive research has allowed breeders to make significant improvements in developing turf-type tall fescue cultivars. Newer varieties and selections possess darker green color, finer leaf texture, lower growth habit, less disease and insect damage, and overall better turf quality. Tall fescue is best known to perform well under drought stress and high temperature conditions.

Presently, research is being conducted to study whether enhanced drought stress and insect resistance occurs where beneficial endophytes exist. Endophytes are naturally occurring fungi that live symbiotically in certain grasses. The endophytes are transmitted from plant to plant through seed. After germination, the endophyte mycelium grows within the sheath, stem, and leaf tissues of the maturing plant, eventually entering the flowering stem and seed. To maintain endophyte viability, seed should be stored at cool temperatures and dry conditions. Although endophytes are a remarkable discovery for the turf grass industry, they can have detrimental effects on grazing livestock. For this reason, endophyte infected grasses should never be used in pasture situations. The levels and toxicity of the endophytes in the plants varies extensively. Endophytes have been found in perennial ryegrass, tall fescue and the fine fescues.

In 2001, the National Turfgrass Evaluation Program (NTEP) distributed seed for a National Tall Fescue Test. Seed was sent to various locations around the country and tests will be evaluated for a number of years under many different conditions. The remnant seed from the 160 entries was analyzed to determine the percentage of seed infected with endophyte.

PROCEDURE

A sample of seed was taken from each entry in the 2001 National Tall Fescue Test and stained using the rose bengal staining method (Saha et al., 1988). In this procedure, seeds were soaked in an alkaline solution (5.0% aqueous ethyl alcohol, 0.5% rose bengal, and 2.5% sodium hydroxide) for 20 to 24 h, rinsed thoroughly in water, and then soaked in a 0.25% aqueous rose bengal solution for 6 h. Samples were then refrigerated until screened. Fifty individual seeds were squashed and analyzed under a microscope at 200X to determine the presence of endophyte.

RESULTS AND DISCUSSION

Results of the endophyte analysis are presented in Table 1. Of the 160 cultivars and selections examined, 146 entries had seeds infected with endophyte. The levels of infection varied extensively: 14 cultivars or selections had no infection, and the highest amount of endophyte detected was 94%. Most cultivars and selections contained moderate to high levels of endophyte compared to similar data from the 1996 National Tall Fescue Test. Since Endophyteinfected seed can lose viability over time and improper storage, it is possible that some turf plots in the 2001 National Tall Fescue Test may have lower levels of infection than indicated in Table 1.
